ABSTRACT

Handwritten word is one of the current manuscript studies that has been intensively researched for many years because it is difficult to identify the styles, patterns, and signatures, especially the Arabic handwriting word. The Arabic letters have special unique characteristic such as dotted letters which can be divided into one dot, two dots and three dots (ظ, ي, ش), the writing direction and certain letters in Arabic script exhibit shape variations when connected to adjacent letters within a word. The Arabic word contains more than one character, which makes it quite a challenge due to the difficulties in recognizing the letter connections, the position-dependent letter shape, and the different writing style, which has led many researchers to separate each Arabic letter from the word, including the dots of the Arabic letters for the purpose of recognition. The Arabic dot letters are often considered as noisy features due to their irregular position on word which resulted in their removal during the preprocessing process, which may lead to incorrect data being extracted during feature extraction. The effect of eliminating dots in Arabic recognition is important because dots are used to distinguish Arabic characters that have a similar letter, such as (ب, ت, ث). This problem can be addressed by applying a global technique that considers the entire image of the Arabic word for feature extraction. Among the image features extracted, feature-based shape has the potential to recognize Arabic word handwriting based on geometric shapes. The triangle geometry method is applied, where the sides of the length of the triangle can be used as feature-based shape by using the appearances of triangle geometry to represent the Arabic word handwriting. Moreover, the multi-stage feature extraction is employed to extract various features such as angles and points of the triangle geometry shape. This study aims to propose the enhanced triangle geometry shape features for Arabic word handwriting recognition using multi-stage feature extraction. The objectives include to propose the triangle geometry shape features to represent the Arabic handwritten word images, to propose a method named Multi-Stage Feature Extraction of Triangle Geometry Shape Appearance Method (MFeTSA) to extract the triangle geometry shape features, and to improve prior straight-line problem solution by using proposed technique of Triangle Coordinate Point Rearrangement (TCPR). A dataset of Arabic (AHDB) and Iran (Iranshahr) is used for this study. The experimental results are obtained by comparing the classification accuracy results with Support Vector Machine, with promising results with high accuracy for both datasets AHDB (76.3825%) and Iranshahr (63.1563%). Statistical validation is used to check the quality of the proposed method, whether it is better than previous methods that use the same triangle geometry method to extract features from triangle geometry. Independent samples t-test is used to validate the proposed method, where the result based on the significant p -values shows that the proposed method is effective for both datasets of Iranshahr and AHDB.

PENAMBAHBAIKAN FTUR BENTUK GEOMETRI SEGITIGA MENGGUNAKAN PENGEKSTRAKAN FITUR PELBAGAI PERINGKAT UNTUK PENGECEMAN TULISAN TANGAN ARAB

ABSTRAK

Kajian mengenai tulisan tangan merupakan salah satu bidang kajian manuskrip semasa yang telah dikaji secara intensif selama bertahun-tahun kerana ia sukar kenal pasti gaya, corak, dan tandatangan, terutamanya tulisan tangan Arab. Huruf Arab mempunyai ciri-ciri unik khas seperti huruf bergelung yang boleh dibahagikan kepada satu titik, dua titik, dan tiga titik (ظ, ي, ش), arah penulisan, dan beberapa huruf tertentu dalam aksara Arab menunjukkan variasi bentuk apabila disambungkan dengan huruf bersebelahan dalam satu perkataan. Perkataan Arab mengandungi lebih daripada satu huruf, yang menjadikannya satu cabaran besar disebabkan kesulitan dalam mengenal pasti hubungan huruf, bentuk huruf bergantung pada kedudukan, dan gaya penulisan yang berbeza, yang telah mendorong ramai penyelidik untuk memisahkan setiap huruf Arab dari perkataan, termasuk titik-titik huruf Arab untuk tujuan pengiktirafan. Huruf titik Arab sering dianggap sebagai ciri-ciri bising kerana kedudukan yang tidak tetap pada perkataan yang mengakibatkan penghapusan semasa proses pra pemrosesan, yang mungkin mengakibatkan data yang salah diekstrak semasa mengekstrak ciri. Kesan penghapusan titik dalam pengiktirafan Arab adalah penting kerana titik digunakan untuk membezakan aksara Arab yang mempunyai huruf yang serupa, seperti (ب, ت, ث). Masalah ini boleh diatasi dengan menerapkan teknik global yang mempertimbangkan keseluruhan imej perkataan Arab untuk ekstrak ciri. Di antara ciri imej yang diekstrak, bentuk berdasarkan ciri mempunyai potensi untuk mengenal pasti tulisan tangan Arab berdasarkan bentuk geometri. Kaedah geometri segitiga digunakan, di mana sisi panjang segitiga boleh digunakan sebagai bentuk berasaskan ciri dengan menggunakan penampilan geometri segitiga untuk mewakili tulisan tangan Arab. Selain itu, pengeluaran ciri berperingkat digunakan untuk mengekstrak pelbagai ciri seperti sudut dan titik bentuk geometri segitiga. Kajian ini bertujuan untuk mengusulkan ciri-ciri bentuk geometri segitiga yang ditingkatkan untuk pengiktirafan tulisan tangan perkataan Arab menggunakan pengeluaran ciri berperingkat. Objektif termasuk mengusulkan ciri bentuk geometri segitiga untuk mewakili imej perkataan tulisan tangan Arab, mengusulkan kaedah yang dinamakan Kaedah Pengeluaran Ciri Berperingkat Bentuk Geometri Segitiga (MFeTSA) untuk mengekstrak ciri bentuk geometri segitiga, dan meningkatkan penyelesaian masalah garis lurus terdahulu dengan menggunakan teknik yang dicadangkan iaitu Teknik Penyatuan Semula Titik Koordinat Segitiga (TCPR). Data set Arab (AHDB) dan Iran (Iranshahr) digunakan untuk kajian ini. Hasil eksperimen diperoleh dengan membandingkan hasil ketepatan klasifikasi dengan Mesin Vektor Sokongan, dengan hasil yang memberangsangkan dengan ketepatan yang tinggi untuk kedua-dua data set AHDB (76.3825%) dan Iranshahr (63.1563%). Pengesahan statistik menggunakan ujian t-sampel independen untuk menilai kualiti kaedah yang dicadangkan, menunjukkan kesan yang berkesan pada kedua-dua data set Iranshahr dan AHDB dengan hasil yang signifikan pada nilai p.

ACKNOWLEDGEMENT

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

First and foremost, I would like to thank and praise Allah the Almighty, my Creator, my Sustainer, for everything I received since the beginning of my life. I would like to extend my appreciation to the Universiti Teknikal Malaysia Melaka (UTeM) for providing the research platform. Thank you also to the Malaysian Ministry of Higher Education (MOHE) and Zamalah Scholarship under UTeM for the financial assistance.

My utmost appreciation goes to my main supervisor, Assoc. Prof. Ts. Dr. Mohd Sanusi Azmi for all his support, advice, and inspiration. His constant patience for guiding and providing priceless insights will forever be remembered. Also, to my co-supervisor, Prof. Dr. Azah Kamilah Draman@Muda, who constantly supported my journey. My special thanks go to my supportive friends from Computational Intelligence and Technology (CIT) for all the help and support I received from them especially Amirul Ramzani Radzid, Eisy Humaira Abdul Azziz, Liew Siaw Hong, and Azrina Tahir during my Ph.D. journey.

Last but not least, from the bottom of my heart a gratitude to my beloved husband, Mohd Nazrien Zaraini, for his encouragement and who has been the pillar of strength in all my endeavors. My eternal love also to my daughter, Burairah, for enlightening my life. I would also like to thank my beloved parents (Arbain Basri and Siti Aisah Samlan) for their endless support, love, and prayers. Finally, thank you to all the individual(s) who had provided me with the assistance, support, and inspiration to embark on my study.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Prior to the widespread integration of technology, individuals utilized paper for written communication and task execution. Despite technological advancements, writing persisted, albeit with the assistance of applications. The uniqueness of individuals' handwriting, characterized by distinct styles, patterns, and signatures, has persisted. To facilitate the seamless transition of handwritten content into digital formats, handwriting recognition has been introduced. This technology empowers computers to understand human handwriting, thereby enhancing accessibility and processing capabilities for digitized information.

Handwriting recognition serves as a crucial technology in translating human handwriting into algorithms comprehensible by computers. This capability plays a pivotal role in the domain of document analysis and recognition. A notable area of ongoing research involves the intricacies of handwritten word recognition, a field that has garnered significant attention over the years. This emphasis stems from the inherent challenges associated with discerning diverse styles, patterns, and signatures present in handwritten word manuscripts.

A specific focus within this research realm is directed towards handwritten Arabic words. The distinct characteristics inherent in the styles and shapes of Arabic letters pose a big challenge in the recognition process. Consequently, understanding and accurately identifying handwritten Arabic words necessitate sophisticated techniques and ongoing advancements in handwriting recognition technology. Arabic handwritten word recognition

is utilized in various applications such as optical character recognition, language translation and digital annotation to convert handwritten Arabic text into digital format for easier processing and analysis. Besides that, the Arabic handwritten word recognition finds application across diverse domains and caters to a broad range of users. The primary target users include researchers and practitioners engaged in document digitization, historical preservation, and linguistic studies within the Arabic-speaking world.

Systems for recognizing handwritten Arabic words have improved drastically over the years. In past decades, many databases of handwritten words (Hull, 1994, M. Pechwitz et al., 2002, Fernando et al., 2003, Al-Ma'adeed et al., 2004) have been developed that can be used as benchmarks for training and testing data for word recognition. Arabic handwritten documents are currently available in many resources in physical form and on the Internet, which poses a challenge for word recognition.

Languages such as Farsi and Urdu use Arabic characters in their writing, which makes the task more difficult due to the different words used, the strength, and the order of the writing (Khosravi and Chalechale, 2022, Rasheed et al., 2022). In relation, numerous researchers (Salem, 2017, Tavoli et al., 2018, Hamida et al., 2020, Kaur and Kumar, 2021, Zohrevand and Imani, 2021, Eltay et al., 2022, Khosravi and Chalechale, 2022, Korichi et al., 2022) have worked hard to overcome this difficulty by developing more competent algorithms and improving existing detection methods and systems.

In a general context, words consist of multiple characters and form integral components of sentences by breaking down individual words. This process involves decomposing words to understand their composition within the structure of a sentence. The word is isolated during the segmentation process, where it is processed from mapping by page, by line and finally the word was isolated from sentence for each of line. In the Arabic

language, words may comprise multiple interconnected components, as exemplified by the term "taskheel" (تشكيل). This characteristic introduces complexities in recognizing individual Arabic letters due to variations in their shapes at the beginning, middle, or end of words. Distinguishing isolated Arabic letters with diverse contextual forms, encompassing initial, middle, and final configurations, including dots, poses challenges in handwritten words due to deviations from precise and standardized writing, as observed in printed texts.

Apart from their distinctive contextual forms, certain Arabic letters sharing similar basic shapes are differentiated by the presence of dots, with variations in the number and placement of dots either above or below the letters. The specific arrangement of dots on Arabic letters is recognized as a physical trait that is frequently misconstrued as noise, particularly when extracting features from Arabic word images, owing to irregular positions in word writing. Moreover, certain Arabic characters, such as "ت", "ب" and "ث" share identical shapes, potentially causing inaccuracies in discerning the meaning of Arabic word scripts when dots are absent or isolated. This situation can further result in the extraction of erroneous data during feature extraction, leading to inaccurate outcomes in classification if the features extracted convey incorrect information from the segmented image.

In earlier studies by Davoudi et al. (2016) and Jayech et al. (2016), segmentation approach was utilized by isolating individual Arabic characters within words, including the isolation of dots from the Arabic characters during the segmentation process. This approach aimed to mitigate potential challenges arising from the adjacency of characters within the same Arabic word. In addition, the poor images of handwritten words, incorrect letter spacing, noise, and poor paper quality further make difficult the recognition of subwords. Furthermore, the difficult connection between the hardware tools and the subsequent

operations such as scanning and binarization poses an additional challenge for the recognition of handwritten Arabic words (Khosravi and Chalechale, 2022).

Therefore, image processing plays an important role in recognizing Arabic handwritten word images. The image processing steps such as pre-processing, segmentation, feature extraction, classification, and validation are applied to process the Arabic handwritten word images by decomposing it into meaningful features that contain valuable information from the Arabic handwritten word image. There are many methods for handwritten words recognition, such as convolutional neural networks, semi-incremental recognition, incremental recognition, line and word segmentation, zoning, and ensemble, which can be used to generate features (Rosyda and Purboyo, 2018). In addition to pre-processing, feature extraction is also an important step in the word recognition process, which is used to extract features from Arabic handwritten word images.

The statistical features often employed by researchers (Fazel et al., 2016, Al-Nuzaili et al., 2017, Tavoli et al., 2018) to recognize Arabic handwritten word images. This is due to the characteristics of Arabic handwritten word images, which can be recognized on the basis of contours and regions which is known as shape representation techniques. The shape features using geometric shapes such as straight lines in different directions have been proposed by Tavoli et al. (2018) for Arabic/Persian handwritten word images, which provide promising results in terms of classification accuracy. However, the method proposed by Tavoli et al. (2018) generates a large size of length for the extracted features, resulting in a longer process.
